# Chapter 1

## Rings

### 1.1 Definition and Theorems

**Definition 1 (Ring).** A ring is a set  $A$  equipped with two binary operations  $+$  (addition) and  $\cdot$  (multiplication) satisfying the following three sets of axioms, called the ring axioms.

1.  $(A, +)$  is an abelian group.
2.  $(A, \cdot)$  is a semigroup.
3. Multiplication is distributive with respect to addition, meaning that
  - $a \cdot (b + c) = (a \cdot b) + (a \cdot c)$  for all  $a, b, c \in A$  (left distributivity).
  - $(b + c) \cdot a = (b \cdot a) + (c \cdot a)$  for all  $a, b, c \in A$  (right distributivity).

A ring is called unitary if it contains the multiplicative identity and commutative if multiplication is commutative.

**Definition 2 (Ideal).**

**Definition 3 (Nilpotent Element and Nilradical).** An element  $x$  of a ring  $A$  is called nilpotent if there exists some positive integer  $n \in \mathbb{N}^+$ , called the index or the degree, such that  $x^n = 0$ .

The set of all nilpotent elements is called the nilradical of the ring and is denoted by  $\text{Nil}(A)$ .

### 1.2 Exercises and Notes

**Example 3.1.** Let  $K$  be a field and  $R = K[X, Y]/(X - XY^2, Y^3)$
