Introduction

Chapter 2

Topological Spaces

2-1

“ \Rightarrow ”: Let $f : X_1 \longrightarrow X_2$ be a homeomorphism and fix a subset (not necessarily open) $U \in \mathcal{T}_1$.

1. Assume U is open in X_1 . Because f is continuous, the image of open subsets are again open, thus $f(U)$ lies in \mathcal{T}_2 .
2. On the other hand, if $f(U)$ is open in X_2 , then since f is bijective we have

$$f^{-1}(f(U)) = U.$$

Because f is continuous, the preimage of open subsets under f is open. We may therefore conclude U is open in X_1 .

We have shown that if f is a homeomorphism, then $f(\mathcal{T}_1) = \mathcal{T}_2$.

“ \Leftarrow ”: Let $f : X_1 \longrightarrow X_2$ be a bijective map such that $f(\mathcal{T}_1) = \mathcal{T}_2$. Consider the inverse map f^{-1} . We want to show f^{-1} is continuous. Fix an open subset $U \in \mathcal{T}_1$. It is

$$(f^{-1})^{-1}(U) = f(U)$$

because f is bijective. Since $f(\mathcal{T}_1) = \mathcal{T}_2$ and U is open, $f(U)$ is open as well. Hence the preimage of U under f^{-1} is open and f^{-1} is continuous.

Now we show that f is also continuous. Again, fix an open subset $V \in \mathcal{T}_2$. The preimage of V under f is just the image of the inverse function. We have already shown that the inverse is continuous. Thus, $f^{-1}(V)$ is open and f is continuous. Since f and f^{-1} exist and are continuous, f is a homeomorphism as desired.

2-2

a)

We show that \mathcal{T} is a topology by verifying the axioms of a topology.

1. Since \mathcal{T} is the collection of all unions of finite intersections of elements of \mathcal{B} , it contains the union of all elements of \mathcal{B} which is just X . The union of empty collection generates the emptyset so $\emptyset \in \mathcal{T}$ as well.
2. Let $\mathcal{U} \subset \mathcal{T}$ be any subset. The elements of \mathcal{U} are unions of finite intersections of elements of \mathcal{B} . Thus, $\bigcup_{U \in \mathcal{U}} U$ is again a union of finite intersections of elements of \mathcal{B} . In other words, \mathcal{T} is closed under union.
3. \mathcal{T} is stable under finite intersections due to distributive property of sets.

b)

2-3

1.

The collection of subset $\mathcal{T}_1 = \{U \subset X \mid X \setminus U \text{ is finite or is all of } X\}$ forms a topology. We show this by verifying the axioms of a topology.

1. It is $X \setminus \emptyset = X$ and $X \setminus X = \emptyset$ which is finite. Thus, $X \in \mathcal{T}_1$ and $\emptyset \in \mathcal{T}_1$.
2. Let $\mathcal{U} \subset \mathcal{T}$ be a subset. By De Morgan's laws we have

$$X \setminus \left(\bigcup_{U \in \mathcal{U}} U \right) = \bigcap_{U \in \mathcal{U}} (X \setminus U).$$

Since each $U \in \mathcal{U}$ lies in \mathcal{T} , the complement $X \setminus U$ is finite or is all of X . Therefore, the intersection of all $X \setminus U$ is again finite or all of X , and we may conclude that \mathcal{T} is stable under arbitrary unions.

3. Use De Morgan's law again.

2.

The collection of subsets $\mathcal{T}_2 = \{U \subset X \mid X \setminus U \text{ is infinite or is empty}\}$ is not a topology. Take $X = \mathbb{Z}$ for example and consider $A = \{1, 2, 3, \dots\}$ and $B = \{-1, -2, -3, \dots\}$. A and B are open because their complements are the non-positive and the non-negative integers respectively. If \mathcal{T}_2 is a topology, it should contain their union $A \cup B = \mathbb{Z} \setminus \{0\}$. However,

$$\mathbb{Z} \setminus (A \cup B) = \mathbb{Z} \setminus (\mathbb{Z} \setminus \{0\}) = \{0\}$$

which is not infinite and thus doesn't lie in \mathcal{T}_2 .

3.

The collection of subsets $\mathcal{T}_3 = \{U \subset X \mid X \setminus U \text{ is countable or all of } X\}$ is a topology PROBABLY.

2-4

Already did somewhere else.

2-5

1. $\text{id}_1 : X \longrightarrow \mathbb{R}^2$ is continuous probably.
2. $\text{id}_2 : \mathbb{R}^2 \longrightarrow X$ is not continuous probably.

2-6

f is continuous because any preimage of a subset $U \subset Z$ under f is open, since any subset in X is open.

For g , the only preimages to check are the emptyset \emptyset and Y . Simply, $g^{-1}(\emptyset) = \emptyset$ and $g^{-1}(Y) = Z$. Both subsets are open in Z , therefore g is continuous.

If h is constant, say $h(Y) = \{p\}$, then $h^{-1}(U) = Y$ if $p \in U$ and $h^{-1}(U) = \emptyset$ if $p \notin U$. In both cases the preimages are open, thus h is continuous. Assume h is continuous but not constant, i.e. there are points $x_1, x_2 \in Y$ such that $h(x_1) \neq h(x_2)$. Z is Hausdorff, so there are disjoint neighbourhoods U of $h(x_1)$ and V of $h(x_2)$. h was assumed to be continuous, so $h^{-1}(U) = Y$ and $h^{-1}(V) = Y$ which is impossible (REALLY?).

2-7

a)

f)

2-8

Firstly, any element in $f(\mathcal{B})$ is open because f is an open map. Fix an open subset V in Y and consider its preimage $f^{-1}(V)$ under f . Because f is continuous, the preimage is open, thus there are base elements B_i with $i \in I$ in \mathcal{B} such that

$$f^{-1}(V) = \bigcup_{i \in I} B_i.$$

The surjectivity of f grants us $f(f^{-1}(V)) = V$, therefore, we have

$$f(f^{-1}(V)) = V = f\left(\bigcup_{i \in I} B_i\right) = \bigcup_{i \in I} f(B_i).$$

Thus, $f(\mathcal{B})$ is a basis of Y .

2-9

2-10

Fix a point y in Y . Since f is surjective, there is an x in X such that $f(x) = y$. X is locally Euclidean, thus there is a neighbourhood U of x that is homeomorphic to \mathbb{R}^n . Moreover, f is locally homeomorphic, so there is a neighbourhood V of x such that the restriction of f under V is a homeomorphism. Then, the intersection $U \cap V = N$ has both of these properties, i.e. N is a neighbourhood of x that is homeomorphic to \mathbb{R}^n and the restriction of f under V is a homeomorphism. $f(N)$ is a neighbourhood of y that is homeomorphic to \mathbb{R}^n , therefore Y is locally Euclidean.

2-11

“ \Rightarrow ”: Let M^0 be a 0-manifold and consider a point $p \in M^0$. First, we show that M^0 is discrete. Since M^0 is locally Euclidean, there is a neighbourhood U of p such that U is homeomorphic to an open subset of \mathbb{R}^0 . But \mathbb{R}^0 contains only one element, thus the only nonempty open subset is \mathbb{R}^0 . Now, a homeomorphism implies bijectivity, we have that $U = \{p\}$. Every singleton set in M^0 is open, so M^0 is a discrete space.

M^0 is also countable because being a manifold implies that it has a countable base and any base must contain all the singleton sets.

“ \Leftarrow ”: Let M^0 be a countable discrete space. M^0 is second-countable because the set of singletons form a countable base. It is also T_2 since each point has itself as its neighbourhood which clearly does not contain any other points. Now let $p \in M^0$ be a point. $\{p\}$ is a neighbourhood of p and it is homeomorphic to \mathbb{R}^0 by the mapping $p \mapsto 0$, thus M^0 is locally Euclidean.

2-12

a

It is $L(b) \cap R(a) = \{c \in X \mid c < b \text{ and } c > a\} = (a, b)$, thus (a, b) is open.

Moreover, we have $L(a) \cup R(b) = \{c \in X \mid c < a \text{ or } c > b\} = X \setminus [a, b]$ which is open, so $[a, b]$ is closed.

b

Let $a, b \in X$ be two distinct points and assume without loss of generality $a < b$. Then, $L(b)$ is open and contains the point a , while $R(a)$ is also open and contains the point b , but $L(b)$ and $R(a)$ are disjoint. Thus, X is Hausdorff.

c

Fix two points $a, b \in X$. By definition, it is

$$\overline{(a, b)} = \bigcap \{ C \subset X \mid (a, b) \subset C \text{ and } C \text{ is closed in } X \}.$$

We have shown that $[a, b]$ is closed in a and clearly contains (a, b) , thus

$$[a, b] \in \{ C \subset X \mid (a, b) \subset C \text{ and } C \text{ is closed in } X \}$$

or in other words

$$\bigcap \{ C \subset X \mid (a, b) \subset C \text{ and } C \text{ is closed in } X \} \subset [a, b]$$

as desired.

When does $\overline{(a, b)} = [a, b]$ hold? Maybe it is pertinent to ask when does it not hold? The equality does not hold if and only if (a, b) is already closed. That means $X \setminus (a, b) = (-\infty, a] \cup [b, \infty)$ is open. I'm not sure, maybe X needs to be countable, finite?

2-13

Let X be a second countable topological space and fix a collection of disjoint open subsets \mathcal{S} , i.e.

$$\mathcal{S} = \{ U \subset X \mid U \text{ is open and for all } U, V \in \mathcal{S} \text{ it is } U \cap V = \emptyset \}.$$

We want to show \mathcal{S} is countable. If \mathcal{B} is a base for X , then for any two members of the collection $U, V \in \mathcal{S}$, we have

$$U = \bigcup_{i \in \mathbb{N}} B_i \quad V = \bigcup_{j \in \mathbb{N}} B_j.$$

Since U and V are disjoint, B_i and B_j are also disjoint for all $i, j \in \mathbb{N}$. Thus, any $U \in \mathcal{S}$ is a union of base elements that is different from any other $V \in \mathcal{S}$. \mathcal{B} is countable, therefore \mathcal{S} must also be.

2-14

Let X be a locally Euclidean space. We show that X is first-countable. Let $p \in X$ be a point, then since X is locally Euclidean, there is a neighbourhood N of p such that N is homeomorphic to \mathbb{R}^n . Thus, we have a sequence of neighbourhoods as \mathbb{R}^n is first-countable, yada yada yada.

Let M be a metric space. I've shown that this is first-countable already.

2-15

a)

Let X be a second-countable space. We want to show that X contains a dense subset that is countable.
